# QSAR, QSPR, statistics, correlation, similarity & descriptors

The tools of trade for the computer based *rational drug design*, particularly if there is no structural information about the *target* (protein) available.

QSAR equations form a quantitative connection between chemical structure and (biological) activity.  $r^2 = 0.99 \text{ se} = 0.27$ 

$$\log(1/C) = k_1 \cdot P_1 + k_2 \cdot P_2 + \ldots + k_n \cdot P_n$$

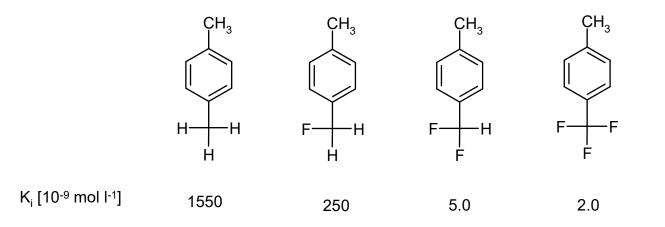

observed

The presence of experimentally measured data for a number of known compounds is required, e.g. from high throughput screening.

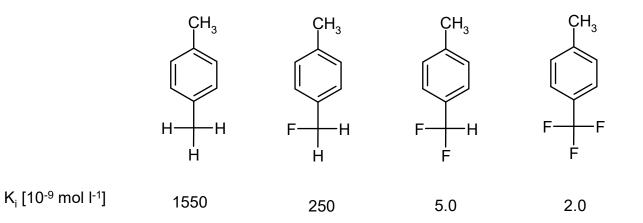

#### Introduction to QSAR (I)

Suppose we have experimentally determined the binding constants for the following compounds

#### Which feature/property is responsible for binding?

#### Introduction to QSAR (II)

Using the number of fluorine atoms as descriptor we obtain following regression equation:

 $r^2 = 0.95$  se = 0.38

$$\log(1/K_i) = a \cdot n_{fluorine} + b$$
  

$$\log(1/K_i) = 1.037 \cdot n_{fluorine} + 5.797$$

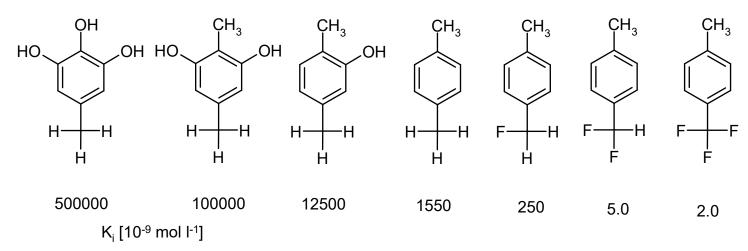

#### Introduction to QSAR (III)

Now we add some additional compounds

Which features/properties are now responsible for binding?

#### Introduction to QSAR (IV)

We assume that following descriptors play a major role:

- number of fluorine atoms
- number of OH groups

$$\log(1/K_i) = a_1 \cdot n_{fluorine} + a_2 \cdot n_{OH} + b$$
  
$$\log(1/K_i) = 1.049 \cdot n_{fluorine} - 0.843 \cdot n_{OH} + 5.768$$

 $r^2 = 0.99$  se = 0.27

9.0

8.0

**8** 7.0

#### Introduction to QSAR (V)

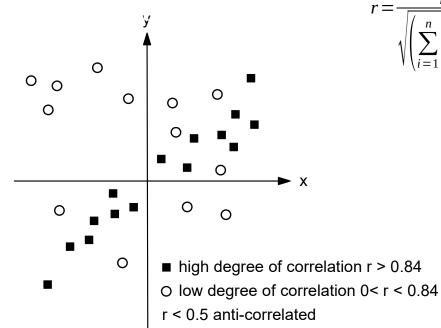

$$\log(1/K_i) = 1.049 \cdot n_{fluorine} - 0.843 \cdot n_{OH} + 5.768$$

 $r^2 = 0.99 \ se = 0.27$ 

Is our prediction sound or just pure coincidence/random?  $\rightarrow$  We will need statistical proof (e.g. using a test set,  $\chi^2$ -test, p-values, cross-validation, boots trapping, ...)

### **Correlation (I)**

The most frequently used value is Pearson's correlation coefficient

$$r = \frac{\sum_{i=1}^{n} (x_i - \overline{x}) (y_i - \overline{y})}{\sqrt{\left(\sum_{i=1}^{n} (x_i - \overline{x})^2\right) \left(\sum_{i=1}^{n} (y_i - \overline{y})^2\right)}} \in [-1...1]$$

 $\rightarrow$  A plot tells more than pure numbers! distribution of the data points, trends, potential outliers, indication of non-linear correlation...

#### **Definition of terms**

QSAR: quantitative structure-activity relationsship QSPR: quantitative structure-property relationship

activity and property can be for example:

 $log(1/K_i)$  constant of binding

 $log(1/IC_{50})$  concentration that produces 50% effect

also physical quantities, such as boiling point, solubility, ... can be addressed

aim: prediction of molecular properties from their structure without the need to perform the experiment.

 $\rightarrow$  in silico instead of in vitro or in vivo

advantages: saves time and resources

#### **Development of QSAR methods over time (I)**

- 1868 A.C.Brown, T.Fraser: Physiological activity is a function of the chemical constitution (composition)
- but: An absolute direct relationship is not possible, only by using differences in activity of already measured compounds.

remember:

- 1865 Suggestion for the structure of benzene by
   A. Kekulé. The chemical structure of most organic compounds at that time was still unknown!
- 1893 H.H.Meyer, C.E.Overton The toxicity of organic compounds is related to their partition between aqueous and lipophilic biological phase.

### **Development of QSAR method over time (II)**

1868 E.Fischer Key and lock principle for enzymes. Again no structural information about enzymes was available!

1930-40 Hammet equation: reactivity of compounds physical, organic, theoretic chemistry

**1964** C.Hansch, J.W.Wilson, S.M.Free, F.Fujita birth of modern QSAR-methods **Hansch analysis** and **Free-Wilson analysis** 

$$\log(1/C) = k_1 \cdot P_1 + k_2 \cdot P_2 + \dots + k_n \cdot P_n$$
  
coefficients (constant) descriptors or variables

linear free energy-related approach

## Descriptors

Approaches that form a mathematical relationsship between numerical quantities (descriptors  $P_i$ ) and the physico-chemical properties of a compound (e.g. biological activity log(1/C)), are called QSAR or QSPR, respectively.

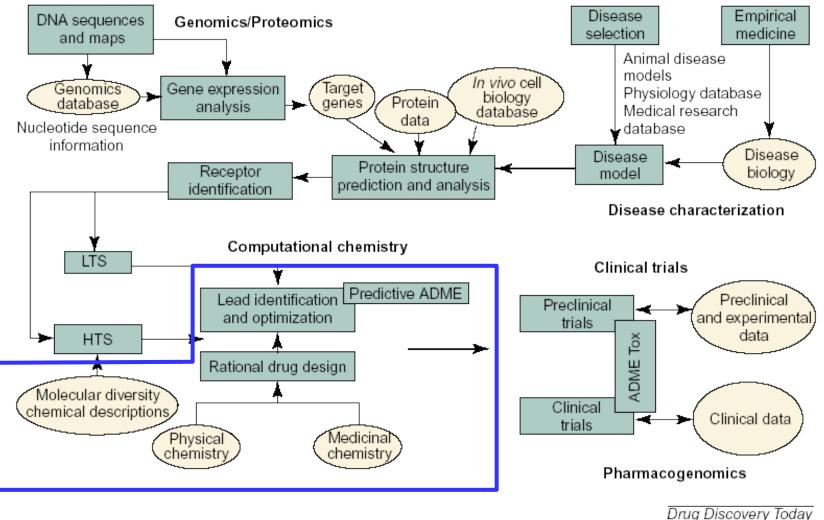

$$\log(1/C) = k_1 \cdot P_1 + k_2 \cdot P_2 + \ldots + k_n \cdot P_n$$

Furthermore, descriptors are used to quantify molecules in the context of diversity analysis and in combinatorial libraries.

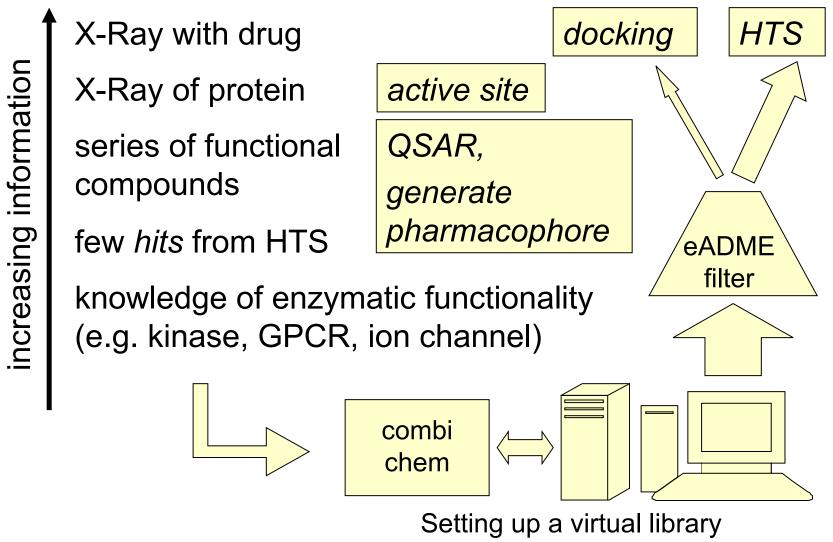

In principle any molecular or numerical property of the compound can by used as descriptors.

More about descriptors and their classification see http://www.codessa-pro.com/descriptors/index.htm

# Flow of information in a *drug discovery pipeline*

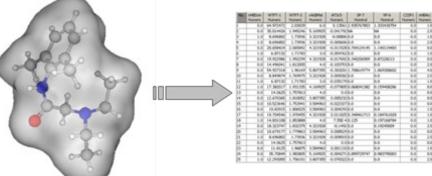

### **Compound selection**

# (Some) descriptors based on molecular properties used to predict ADME properties

logP water/octanol partitioning coefficient Lipinski's rule of five topological indices polar surface area similary / dissimilarity

QSAR quantitative structure activity relationship QSPR quantitative structure property rel.

#### "1D" descriptors (I)

For some descriptors we need only the information that can be obtained from sum formula of the compound. Examples: molecular weight, total charge, number of halogen atoms, ...

Further 1-dimensional descriptors are obtained by the summation of atomic contributions. Examples:

sum of the atomic polarizabilities

refractivity (molar refractivity,  $M_R$ )

 $M_R = (n^2 - 1) MW / (n^2 + 2) d$ 

with refractive index *n*, density *d*, molecular weight *MW* 

Depends on the polarizability and moreover contains information about the molecular volume (MW / d)

## logP (l)

The *n*-octanol / water partition coefficient, respectively its logarithmic value is called logP.

Frequently used to estimate the membrane permeability and the bioavailability of compounds, since an orally administered drug must be enough lipophilic to cross the lipid bilayer of the membranes, and on the other hand, must be sufficiently water soluble to be transported in the blood and the lymph.

hydrophilic –4.0 < logP < +8.0 lipophilic

glucose –3.24

flurbiprofene +4.16

"typical" drugs < 5.0

Modern Methods in Drug Discovery WS21/22

## logP (II)

An increasing number of methods to predict logP have been developed:

Based on molecular fragments (atoms, groups, and larger fragments)

ClogP Leo, Hansch et al. *J.Med.Chem.* **18** (1975) 865. problem: non-parameterized fragments (occur up to 25% of all compounds in substance libraries)

Based on atom types (similar to force field atom types)

- SlogP S.A. Wildman & G.M.Crippen *J.Chem.Inf.Comput.Sci.* **39** (1999) 868.
- AlogP, MlogP, XlogP...

Parameters for each method were obtained using a mathematical fitting procedure (linear regression, neural net,...)

Review: R.Mannhold & H.van de Waaterbeemd, J.Comput.-Aided Mol.Des. **15** (2001) 337-354.

5th lecture

## logP (III)

Further logP prediction methods apply whole molecule properties, such as

- molecular surface (polar/non-polar area, or their electrostatic properties = electrostatic potential)
- dipole moment and molecular polarizability
- ratio of volume / surface (globularity)

Example: Neural net trained with quantum chemical data logP T. Clark et al. *J.Mol.Model.* **3** (1997) 142.

### "1D" descriptors (II)

Further atomic descriptors use information based on empirical atom types like in force fields. Examples:

- Number of halogen atoms
- Number of sp<sup>3</sup> hybridized carbon atoms
- Number of H-bond acceptors (N, O, S)
- Number of H-bond donors (OH, NH, SH)
- Number of aromatic rings
- Number of COOH groups
- Number of ionizable groups (NH<sub>2</sub>, COOH)
- . . .
- Number of freely rotatable bonds (single bonds that are not in a ring)

#### **Fingerprints as binary descriptors** (a) (b) (c) Lipophilic Acceptor 3-L Acceptor Donor Aromatic 2-D 2-D (d) (f) (e) 001101010000101010100000110101000000001 (g) Drug Discovery Today: HTS supplement

**Figure 2.** Schematic illustration of primary methods used in molecular fingerprint creation. (a) Create 2-D and 3-D model of molecule; (b) deconstruct the molecule into pharmacophoric elements; (c) generate conformational models; (d) deconstruct the molecule into topological/substructural elements; (e) determine distance between pharmacophoric groups using bond counts; (f) determine 2-, 3- or 4-center distance combinations of pharmacophoric groups for each conformer; and (g) determine the presence or absence of each descriptor element and combine to create a binary fingerprint.

#### Lipinski's Rule of 5

Combination of descriptors to estimate intestinal absorption. Insufficient uptake of compounds, if

Molecular weight > 500

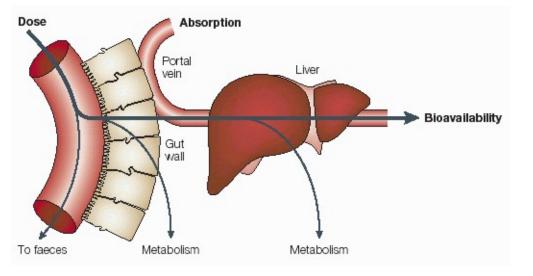

logP > 5.0

slow diffusion too lipophilic

> 5 H-bond donors (OH and NH)

to many H-bonds with the head

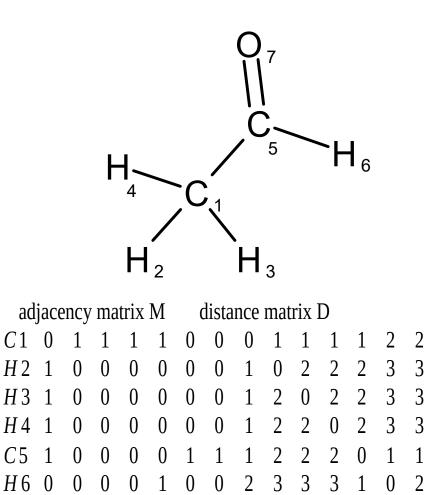

>10 H-bond acceptors (N and O atoms) groups of the membrane

#### 2D descriptors (II)

The essential topological properties of a molecules are the degree of branching and the molecular shape.

An sp<sup>3</sup> hybridized carbon has got 4 valences, an sp<sup>2</sup> carbon only 3.

Thus the ratio of the actual branching degree to the theoretically possible branching degree can be used as descriptor as it is related to the saturation.

#### 2D descriptors (III)

Common definitions:

 $Z_i$  ordinary number (H=1, C=6, N=7, LP=0)

 $h_i$  number of H atoms bonded to atom *i* 

 $d_i$  number of non-hydrogen atoms bonded to atom i

Descriptors accounting for the degree of branching and the flexibility of a molecule:

Kier & Hall Connectivity Indices  $p_i$  sum of *s* and *p* valence electrons of atom *i*  $v_i = (p_i - h_i) / (Z_i - p_i - 1)$  for all non-hydrogen (heavy) atoms

#### **Kier and Hall Connectivity Indices**

$$Z_i$$
 ordinary number (H=1, C=6, LP=0)

 $d_i$  number of heavy atoms bonded to atom i

 $p_i$  number of s and p valence electrons of atom i

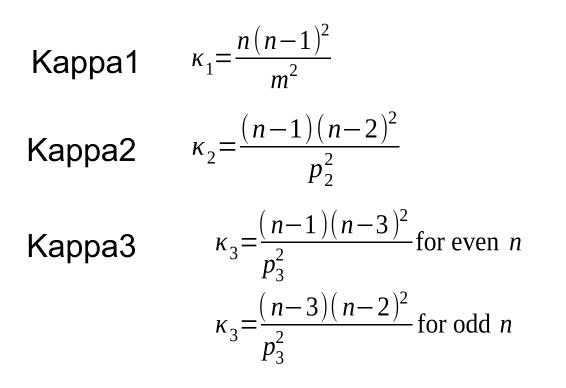

$$v_i = (p_i - h_i) / (Z_i - p_i - 1)$$
 for all heavy atoms  
Chi0 Oth order  $\chi_0 = \sum_i \frac{1}{\sqrt{d_i}}$  for all heavy atom with  $d_i > 0$ 

**Chi1 1st order** 
$$\chi_1 = \sum_i \sum_{j>i} \frac{1}{\sqrt{d_i d_j}}$$
 for all heavy atoms if   
*i* is bonded to *j*

ChiOv Valence index  $\chi_{0v} = \sum_{i} \frac{1}{\sqrt{v_i}}$  for all heavy atoms with  $v_i > 0$ 

#### Kier and Hall Shape Indices (I)

*n* number of heavy atoms (non-hydrogen atoms) *m* total number of bonds between all heavy atoms  $p_2$  number of paths of length 2  $p_3$  number of paths of length 3 from the distance matrix **D** 

#### Kier and Hall Shape Indices (II)

Relating the atoms to sp<sup>3</sup>-hybridized carbon atoms yields the Kappa alpha indices

 $\alpha = \sum_{i}^{n} \frac{r_{i}}{r_{c}-1} \quad \begin{array}{l} r_{i} \text{ covalence radius of atom } i \\ r_{c} \text{ covalence radius of an sp}^{3} \\ \text{ carbon atom} \\ \kappa_{\alpha 1} = \frac{s(s-1)^{2}}{(m+\alpha)^{2}} \text{ with } s = n+\alpha \end{array}$ 

element	hybridi- zation	α
С	sp <sup>3</sup>	0
С	sp <sup>2</sup>	-0.13
С	sp	-0.22
Ν	sp <sup>3</sup>	-0.04

#### Balaban, Wiener, and Zagreb Indices

*n* number of heavy atoms (non-hydrogen atoms) *m* total number of bonds between all heavy atoms  $d_i$  number of heavy atoms bonded to atom *i* 

 $w_i = \sum_{i \neq j} D_{ij}$  Sum of the off-diagonal matrix elements of atom *i* in the distance matrix **D** BalabanJ  $\frac{m}{m-n+1} \sum \frac{1}{\sqrt{w_i w_j}}$ WienerJ (path number)  $\frac{1}{2}\sum_{i}^{n} w_{i}$  Correlates with the boiling points of alkanes Wiener polarity  $\frac{1}{2}\sum_{i=1}^{n} w_{i}$  if  $D_{ij} \ge 3$ **Zagreb index**  $\sum_{i} d_i^2$  for all heavy atoms *i* 5th lecture Modern Methods in Drug Discovery WS21/22 28

#### What message do topological indices contain?

topological indices are associated with the

- degree of branching in the molecule
- size and spacial extention of the molecule
- structural flexibility

Usually it is not possible to correlate a chemical property directly by using only one single index.

Although topological indices encode the same properties as fingerprints do, they are harder to interpret, but can be generated numerically more easily.

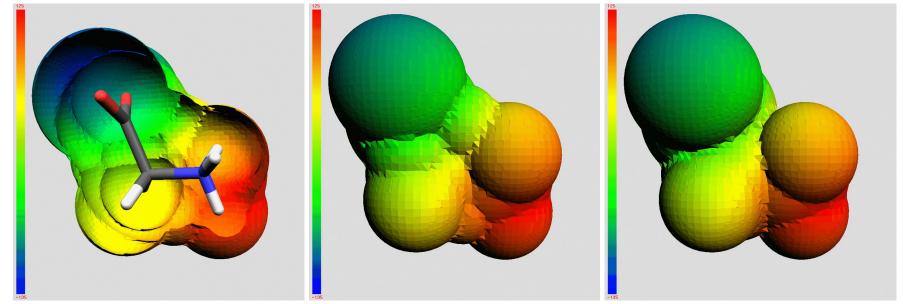

#### **3D descriptors**

Descriptors using the atomic coordinates (x,y,z) of a molecules are therefore called 3D descriptors.

As a consequence they usually depend on the conformation. (rotation around single bonds causes leads to other conformations)

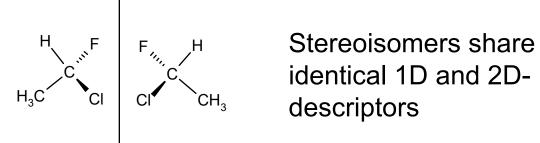

Examples:

van der Waals volume, molecular surface, polar surface, electrostatic potential (ESP), dipole moment

#### **Chiralty Descriptors**

Most biological interactions are stereospecific e.g. ligand binding

Ideas for including chirality:

 Using differences of the van der Waals volume or the electrostatic potential after superposition (rotation)

- Adding +1/-1 to chiral centers in the adjacency matrix while computing topological descriptors
- Modifying the sign of 1D-descriptors (electronegativity, size, polarizability,...) with respect to the enantiomer

## Chosing the right compounds (I)

To derive meaningful QSAR predictions we need

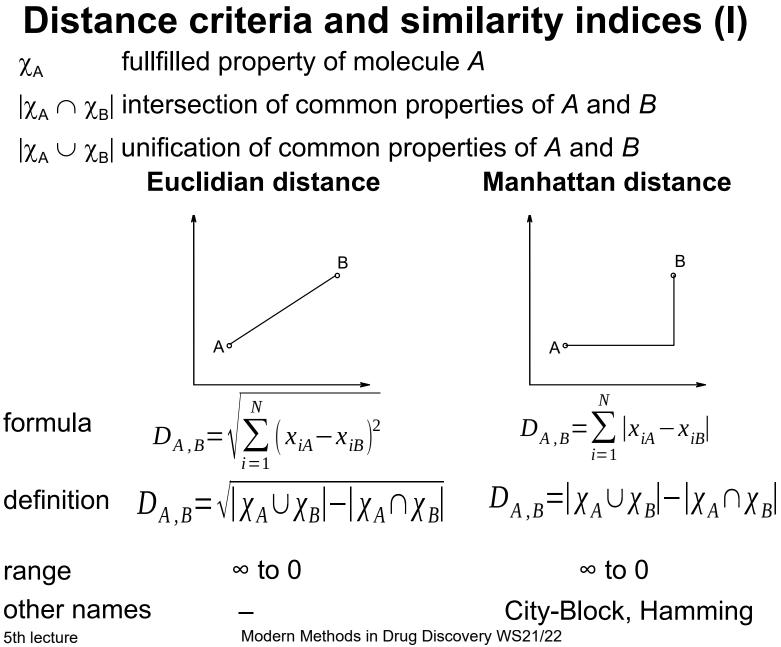

- A sufficient number of compounds
- Structurally diverse compounds

statistically sound tradeoff between count and similarity

How similar are compounds to each other ?

 $\rightarrow$  Clustering using distance criteria that are based on the descriptors

#### **Distance crtiteria and similarity indices (II)**

Soergel distanceTanimoto index $D_{A,B} = \sum_{i=1}^{N} |x_{iA} - x_{iB}| / \sum_{i=1}^{N} \max(x_{iA}, x_{iB})$  $S_{A,B} = \left(\sum_{i=1}^{N} x_{iA} x_{iB}\right) / \left(\sum_{i=1}^{N} (x_{iA})^2 + \sum_{i=1}^{N} (x_{iB})^2 - \sum_{i=1}^{N} x_{iA} x_{iB}\right)$  $D_{A,B} = |\chi_A \cup \chi_B| - |\chi_A \cap \chi_B| / |\chi_A \cup \chi_B|$  $S_{A,B} = |\chi_A \cap \chi_B| / |\chi_A \cup \chi_B|$ 1 to 0-0.333 to +1 (continous values)<br/>0 to +1 (binary on/off values)-Jaccard coefficient

For binary (dichotomous) values the Soergel distance is complementary to the Tanimoto index

#### Distance criteria and similarity indices (III)

#### **Dice coefficient**

$$S_{A,B} = \left(2\sum_{i=1}^{N} x_{iA} x_{iB}\right) / \left(\sum_{i=1}^{N} (x_{iA})^{2} + \sum_{i=1}^{N} (x_{iB})^{2}\right)$$

$$S_{A,B} = 2|\chi_A \cap \chi_B|/(|\chi_A| + |\chi_B|)$$

-1 to +1 0 to +1

Hodgkin index Czekanowski coefficient Sørensen coefficient

monotonic with the Tanimoto index

#### **Cosinus coefficient**

$$S_{A,B} = \left(\sum_{i=1}^{N} x_{iA} x_{iB}\right) / \sqrt{\sum_{i=1}^{N} (x_{iA})^2 \cdot \sum_{i=1}^{N} (x_{iB})^2}$$

$$S_{A,B} = |\chi_A \cap \chi_B| / \sqrt{|\chi_A| |\chi_B|}$$

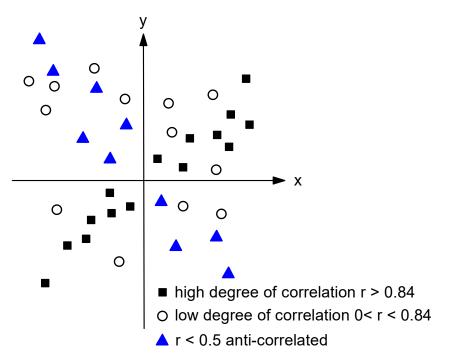

0 to +1 (continous values) 0 to +1 (binary on/off values)

> Carbo index Ochiai coefficient

Highly correlated to the Tanimoto index

## **Correlation between descriptors (I)**

Descriptors can also be inter-correlated (colinear) to each other  $\rightarrow$  redundant information should be excluded

Usually we will have a wealth of descriptors (much more than the available molecules) to chose from. To obtain a reasonable combination in our QSAR equation, multivariate methods of statistics or other selection procedures must be applied. 5th lecture Modern Methods in Drug Discovery WS21/22

### **Correlation between descriptors (II)**

How many descriptors can be used in a QSAR equation?

Rule of thumb:

per descriptor used, at least 5 molecules (data points) should be present

otherwise the possibility of finding a coincidental correlation is too high (as we will see later).

- $\geq$ 10 molecules  $\rightarrow$  2 descriptors
- $\geq$ 15 molecules  $\rightarrow$  3 descriptors...

(Ockham's razor: it's possible to fit anything to anything) Therefore:

Principle of parsimony, use the most simple explanation.

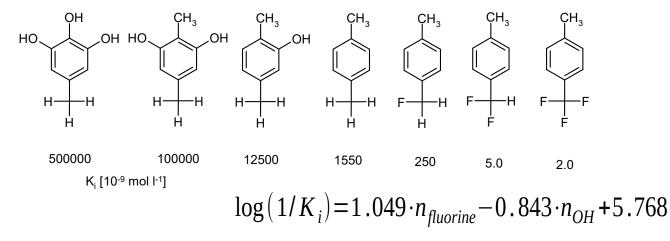

## **Deriving QSAR equations (I)**

After removing the inter-correlated descriptors, we have to determine the coefficients  $k_i$  for those descriptors that appear in the QSAR equation.

Such multiple linear regression analysis (*least square fit* of the according coefficients) is performed by statistics programs

There are several ways to proceed:

1. Using the descriptor that shows the best correlation to the predicted property first and adding stepwise descriptors that yield the best improvement (**forward regression**)

Modern Methods in Drug Discovery WS21/22

#### **Deriving QSAR equations (II)**

2. Using all available descriptors first, and removing stepwise those descriptors that worsen the correlation fewest (**backward regression/elimination**)

3. Determining the best combination of the available descriptors for given number of descriptors appearing in the QSAR equation (2,3,4,...) (**best combination regression**)

This is usually not possible due to the exponential runtime

Problem of forward and backward regression: Risk of local minima

Problem: Which descriptors are relevant or significant? Determination of such descriptors see lecture 6
